01 基本信息

- Title: OmicSync: Reliability-Aware Spatial Multi-Omics Clustering with Evidence-Constrained LLM Reasoning
- Authors: Rabeya Tus Sadia, Qiang Ye, Qiang Cheng
- Affiliation: Department of Computer Science / Mathematics, University of Kentucky
- Publication venue: arXiv (preprint)
- URL: <http://arxiv.org/abs/2608.22785v2>
- PDF URL: <https://arxiv.org/pdf/2608.22785v2>
- Published: 2026-08-24
- Code/data availability: Not 核验
- Key modalities: RNA (gene expression), ADT (surface protein), histology (H&E image patches), spatial coordinates
- Key datasets: Four 10x CytAssist FFPE spatial proteomics benchmarks - Human Tonsil, Human Breast Cancer, Human Glioblastoma, Human Tonsil with Add-on Antibodies [Paper: PDF p. 11]
- Core models: KAN-GCN backbone, CrossModalTransformer, UncertaintyMoE (MC-Dropout-gated mixture-of-experts), ClusteringHead (Student's t-distribution), CellTypeHead (MLP), Llama-3.3-70B (reasoning module) [Paper: PDF p. 4-7, 9]

02 一句话总结

OmicSync 是一个可靠性感知的 spatial multi-omics 聚类框架，通过耦合 KAN-GCN-based 多模态融合、不确定性感知 MoE 路由、软聚类头与五策略 LLM 推理模块，为每个组织 spot 输出可审计的 domain 分配、assignment confidence、epistemic routing uncertainty、modality-routing weights 及自然语言解释；其扩展变体 OmicSync-R 进一步利用 REINFORCE 将自动计算的推理质量分数（GR/CA/SC）作为非可微奖励信号，闭环优化 latent 表示 [Paper: PDF p. 1, 7, 9-10].

03 研究问题

- 如何在 spatial multi-omics domain clustering 中同时建模并量化 assignment reliability（而非仅输出硬聚类标签）？[Paper: PDF p. 1]
- 如何将模型内部衍生的多维可靠性信号（confidence、uncertainty、modality routing、neighbourhood evidence）结构化并约束 LLM 生成 faithful、spot-level 的自然语言解释？[Paper: PDF p. 2, 6]
- 是否能将推理质量（faithfulness）作为非可微 reward 反馈至 clustering 模块，实现 reasoning-guided latent space refinement，而无需反向传播至 LLM？[Paper: PDF p. 7, 9]
- 在缺乏 ground-truth domain 标注的临床 FFPE 数据上，如何设计可复现、跨数据集鲁棒的评估协议？[Paper: PDF p. 11]

04 研究背景与发展路径

- Spatial domain discovery : 从早期 RNA-only + k-means/Leiden [9] -> 图神经网络整合空间邻域 (STAGATE [10], GraphST [11]) -> 多模态融合 (SpatialGlue [7], MISO [6], GROVER [5], COSMOS [8]) [Paper: PDF p. 2]。但所有现有方法均只输出 flat partition, 缺失 reliability、why、modality attribution [Paper: PDF p. 1-2]。
- Explainability in spatial omics : 此前限于 attention 可视化或 SHAP [12], 未结合 LLM 与模型内生信号生成结构化解释; 单细胞领域虽有 LLM 应用 (cell-type annotation [14], pathway summarisation [15]), 但未与 spatial clustering 模型耦合 [Paper: PDF p. 3]。
- Uncertainty & MoE : MC dropout [17] 提供 epistemic uncertainty 近似; sparse MoE [16] 支持模态特异专家路由; OmicSync 首次将二者结合用于 spatial multi-omics routing uncertainty 估计 [Paper: PDF p. 3]。
- REINFORCE for non-differentiable feedback : 已在 NLP 中用于序列级目标优化 [19]; OmicSync-R 首次将其用于 spatial domain clustering, 以 reasoning-quality 为 reward 引导 latent structure [Paper: PDF p. 3-4]。

05 论文识别的核心痛点

Pain point / Manifestation / Cause or author explanation / Evidence from the paper

Pain point: Opaque clustering outputs

Manifestation: Existing methods return only flat spot partitions without reliability indicators, modality attribution, or justification for individual assignments [Paper: PDF p. 1]

Cause or author explanation: Most spatial domain discovery methods treat interpretability as external visualization, not intrinsic model output [Paper: PDF p. 2]

Evidence from the paper: Abstract: “most spatial domain discovery methods provide only cluster assignments, without indicating assignment reliability, modality contributions, or why a domain decision should be trusted” [Paper: PDF p. 1]; Introduction: “return only one type of output, namely, a flat partition... without indicating which assignments are reliable, why... or which molecular modality primarily drove each assignment” [Paper: PDF p. 1]

Pain point: Downstream error propagation

Manifestation: Boundary spots or degraded-data spots assigned with equal weight as confident ones may propagate errors into differential expression, ligand-receptor inference, etc. [Paper: PDF p. 1]

Cause or author explanation: Lack of per-spot confidence quantification prevents downstream analyses from weighting assignments appropriately [Paper: PDF p. 1]

Evidence from the paper: Introduction: “downstream analyses that treat all spot assignments as equally reliable may propagate clustering errors into biological conclusions, particularly for boundary spots where adjacent domains overlap or for spots affected by degraded data quality” [Paper: PDF p. 1]

Pain point: Unconstrained LLM explanations

Manifestation: Prior LLM use in omics lacks grounding in model-derived evidence, risking hallucination or biologically unsupported claims [Paper: PDF p. 3]

Cause or author explanation: No existing work couples LLM with trained spatial clustering model through structured, model-derived evidence [Paper: PDF p. 3]

Evidence from the paper: Background 2.2: “To our knowledge, however, existing work has not coupled an LLM with a trained spatial clustering model through structured, model-derived evidence to generate reliability-aware explanations for individual spots” [Paper: PDF p. 3]

Pain point: ARI-SilC trade-off in contrastive learning

Manifestation: Fixed spatial exclusion radius (nhops) harms performance on heterogeneous tissues (e.g., tumor-stroma boundaries) and homogeneous tissues (e.g., germinal centers) alike [Paper: PDF p. 7]

Cause or author explanation: Homogeneous tissue requires broader exclusion to avoid treating similar neighbors as negatives; heterogeneous tissue needs tighter exclusion to retain transcriptionally distinct neighbors [Paper: PDF p. 7]

Evidence from the paper: Section 4.8: “Homogeneous tissue… uses nhops = 2… Heterogeneous tissue… uses nhops = 1… This schedule allows the contrastive loss to promote local spatial consistency early in training, while allowing the clustering and reconstruction objectives to play a larger role later” [Paper: PDF p. 7]

06 核心思想

- Reliability as first-class output：将 assignment confidence $\$c_i\$$, epistemic routing uncertainty $\$u_i\$$, modality-routing weights $\$\bar{g}_i\$$ 作为模型原生输出，而非后处理指标 [Paper: PDF p. 3-4, Eq. 3-4, 13].
- Evidence-constrained reasoning：将五类模型内生信号（domain assignment, confidence, modality routing, uncertainty, neighbourhood composition）组装为 structured evidence dictionary，作为 LLM 唯一输入，禁止引入外部知识，确保解释可审计、可追溯 [Paper: PDF p. 6, 8].
- Five-strategy reasoning taxonomy：Standard / Stepwise / Counterfactual / Contrastive / Uncertainty 五种 prompt 模板，覆盖不同解释需求，其中 Stepwise 强制五阶段显式引用分子、模态、空间、不确定性证据 [Paper: PDF p. 8-9, Fig. 3A].
- Reasoning-clustering loop via REINFORCE：OmicSync-R 不反向传播至 LLM，而是将 GR/CA/SC 加权和 $\$R_i\$$ 作为 reward，通过 policy gradient 更新 ClusteringHead 的 soft assignment distribution $\$q_i\$$ ，使 reasoning coherence 正向塑造 latent structure [Paper: PDF p. 9-10, Eq. 19-24].

07 方法总览

OmicSync 是端到端可训练框架，输入为 $\$N\$$ 个 spot 的 RNA ($\$X_1\$$), ADT ($\$X_2\$$), histology ($\$X_3\$$), spatial coordinates ($\$C\$$)，输出为共享 latent 表示 $\$Z \in \mathbb{R}^{N \times d}\$$ 和三类可靠性信号。架构含六大组件：(1) SpatialPositionEncoder 对坐标进行正弦编码并注入各模态特征；(2) KAN-GCN encoders + intra-modality attention 分别处理各模态的空间/特征邻接图；(3) CrossModalTransformer 对齐三模态 token 并交互增强；(4) UncertaintyMoE 通过 MC-Dropout 估计 $\$\bar{g}_i\$$ 与 $\$u_i\$$ ；(5) ClusteringHead 基于 Student’s t-kernel 输出 soft assignment $\$Q\$$ 与 $\$c_i\$$ ；(6) CellTypeHead（伪标签监督）与 ImputationHeads（自监督重建）提供辅助正则。训练目标为加权多任务损失 $\$L_{\text{OmicSync}}\$$ [Paper: PDF p. 3-7, Eq. 17]. OmicSync-R 在此基础上增加 REINFORCE 项 $\$L_{\text{reinforce}}\$$ ，以 reasoning-quality $\$R_i\$$ 为 reward 更新 $\$q_i\$$ [Paper: PDF p. 9-10, Eq. 23-24].

08 核心模块拆解

Module / Function / Why needed / Input and output / Supporting evidence / Known or expected effect of removal

Module: SpatialPositionEncoder

Function: Encodes absolute spot coordinates $\$(c_{i,x}, c_{i,y})\$$ into sinusoidal 2D positional embedding $\$PE_m(c_i)\$$ and adds it to modality features before GCN

Why needed: To distinguish spots with identical molecular profiles but different tissue locations (e.g., germinal center edge vs. center), incorporating spatial context beyond molecular composition

Input and output: Input: $\$c_i \in \mathbb{R}^2\$$; Output: $\$PE_m(c_i) \in \mathbb{R}^{d_m}\$$ [Eq. 7]

Supporting evidence: Section 4.2: “This design allows the model to incorporate spatial context and tissue architecture that are not captured by molecular composition alone” [Paper: PDF p. 5]; Fig. 1 shows positional encoding feeding into graph encoders [Paper: PDF p. 4]

Known or expected effect of removal: Loss of spatial architectural awareness; reduced separation

of spatially proximal but molecularly distinct domains (e.g., tumor-stroma interface) [Analysis]

Module: UncertaintyMoE

Function: Fuses cross-modally enriched embeddings e'_1, e'_2, e'_3 via MC-Dropout-gated softmax router; computes mean routing vector $\bar{g}_i$ and epistemic routing uncertainty $u_i = \sum_m \mathrm{Var}_t[g_{i,m,t}]$

Why needed: To quantify both which modality dominates fusion ($\bar{g}_i$) and how stable that dominance is under stochastic perturbation (u_i), enabling uncertainty-aware interpretation

Input and output: Input: $e_i = \frac{1}{3} \sum e'_{m,i}$; Output: $\bar{g}_i \in [0,1]^3$, $u_i \in \mathbb{R}_{\geq 0}$ [Eq. 11-13]

Supporting evidence: Section 4.5: “The mean gate values $\bar{g}_i \dots$ are used as an interpretable proxy for the relative contribution... The scalar $u_i \dots$ is defined as the epistemic routing uncertainty” [Paper: PDF p. 6-7]; Fig. 1 shows UncertaintyMoE producing “Modality Routing Weights” and “Routing Uncertainty” [Paper: PDF p. 4]

Known or expected effect of removal: Removal eliminates modality attribution and uncertainty quantification; reasoning module loses two core signals ($\bar{g}_i$, u_i), collapsing to single-modality or deterministic fusion [Analysis]

Module: ClusteringHead

Function: Projects normalized latent z_i onto K learnable centroids $\{\mu_k\}$ using Student’s t-kernel to produce soft assignment $q_{ik} = (1 +$

Why needed: $\hat{z}_i - \mu_k$

Input and output: $2)^{-1} / \sum_k (\dots)$; defines $\hat{k}_i = \arg \max_k q_{ik}$, $c_i = \max_k q_{ik}$

Supporting evidence: To enable soft, probabilistic clustering essential for confidence estimation, runner-up analysis, and sampling-based REINFORCE updates

Known or expected effect of removal: Input: $\hat{z}_i = z_i /$

Field 7: $z_i /$

Field 8: z_i ; Output: $q_i \in [0,1]^K$, $c_i \in [0,1]$ [Eq. 15-16]

Field 9: Section 4.6: “The predicted domain for spot i is $\hat{k}_i = \arg \max_k q_{ik}$, and the assignment confidence is defined as $c_i = \max_k q_{ik}$ ” [Paper: PDF p. 7]; Eq. 15 explicitly defines q_{ik} [Paper: PDF p. 7]

Field 10: Removal eliminates soft assignment, confidence, and runner-up signals; Task C reasoning cannot sample $a_i \sim \text{Categorical}(q_i)$ [Eq. 19], breaking OmicSync-R’s REINFORCE loop [Paper: PDF p. 9]

Module: Evidence-constrained reasoning module

Function: Takes structured evidence dictionary (domain, c_i , $\bar{g}_i$, u_i , top markers, 5-nearest neighbours) and generates natural-language justification $J^{(r)}_i$ for strategy r using Llama-3.3-70B

Why needed: To translate quantitative reliability signals into human-understandable, auditable explanations, preventing hallucination by constraining LLM to supplied evidence only

Input and output: Input: Evidence dictionary (5 components); Output: $J^{(r)}_i$ (text) [Paper: PDF p. 6, 8]

Supporting evidence: Section 6.1: “This coupling is designed to make the explanations auditable, so that each generated justification can be traced back to the model-derived evidence” [Paper: PDF p. 8]; Section 6.3: System prompt forbids introducing gene names, protein names, or facts absent from evidence [Paper: PDF p. 9]

Known or expected effect of removal: Removal reduces framework to standard clustering; no spot-level reliability reports, no faithfulness metrics (GR/CA/SC), no reasoning-guided training possible [Paper: PDF p. 6-9]

Module: OmicSync-R REINFORCE loop

Function: At reasoning-update epochs, samples $a_i \sim \text{Categorical}(q_i)$, constructs evidence dictionary conditioned on a_i , queries LLM, scores $R_i = w_1 GR_i + w_2 CA_i + w_3 SC_i$, computes $L_{\text{reinforce}} = -\frac{1}{\log}$

Why needed: S_R

Input and output: $\sum_{i \in S_R} \text{sg}(R_i - b_t) \log q_{i,a_i}$

Supporting evidence: To close the reasoning-clustering loop without backpropagating through LLM, using reasoning coherence as auxiliary signal to shape latent space

Known or expected effect of removal: Input: q_i , S_R (domain-stratified sample); Output: $L_{\text{reinforce}}$ scalar loss [Eq. 23]
 Field 7: Section 7.1: “The language model and text-scoring procedure are treated as black-box components… the scalar reward is used to weight the log-probability of the sampled cluster assignment” [Paper: PDF p. 9]; Eq. 23 defines $L_{\text{reinforce}}$ [Paper: PDF p. 10]
 Field 8: Without this, OmicSync-R reverts to base OmicSync; no improvement in ARI (+0.99) or other metrics on Human Breast Cancer [Table 7, Paper: PDF p. 17]

09 关键公式与符号

ID / Formula / Meaning / Page / Notes

ID: Eq. 2

Formula: $\sum_{k=1}^K q_{ik} = 1, i = 1, \dots, N$

Meaning: Soft assignment matrix Q rows sum to 1 (probability simplex)

Page: p. 3

Notes: Defines q_{ik} as per-spot domain probability distribution [Paper: PDF p. 3]

ID: Eq. 3

Formula: $\hat{k}_i = \arg \max_{1 \leq k \leq K} q_{ik}, c_i = \max_{1 \leq k \leq K} q_{ik}$

Meaning: Hard assignment $\hat{k}_i$ and assignment confidence c_i

Page: p. 4

Notes: Core reliability signal; used in Task C evidence dictionary and OmicSync-R sampling [Paper: PDF p. 4, 9]

ID: Eq. 4

Formula: $\sum_{m=1}^3 G_{im} = 1, i = 1, \dots, N$

Meaning: Modality-routing matrix G rows sum to 1 (RNA/ADT/histology weights)

Page: p. 4

Notes: $\bar{g}_i$ (mean gate output) is i -th row of G ; used in evidence dictionary [Paper: PDF p. 4, 6]

ID: Eq. 7

Formula: $PE_m(c_i) = W^{PE}_m [\sin(c_{i,x}f), \cos(c_{i,x}f), \sin(c_{i,y}f), \cos(c_{i,y}f)]^{\text{top}}$

Meaning: Sinusoidal 2D positional encoding of spot coordinate c_i

Page: p. 5

Notes: Injects absolute location bias into modality features before GCN [Paper: PDF p. 5]

ID: Eq. 11

Formula: $g_{i,t} = \text{softmax}(W_g \cdot \text{Dropout}_t(\bar{e}_i)) \in [0,1]^3$

Meaning: MC-Dropout sample t of modality-routing logits for spot i

Page: p. 6

Notes: Foundation for computing $\bar{g}_i$ (mean) and u_i (variance) [Eq. 12-13, Paper: PDF p. 6]

ID: Eq. 13

Formula: $u_i = \sum_{m=1}^3 \text{Var}_{t=1, \dots, T}[g_{i,m,t}]$

Meaning: Epistemic routing uncertainty for spot i

Page: p. 6

Notes: Defined as sum of variances across MC-Dropout samples; key reliability signal [Paper: PDF p. 6]

ID: Eq. 15

Formula: $q_{ik} = \frac{1 + \hat{z}_i - \mu_k}{\sum_{k'=1}^K (1 + \hat{z}_i - \mu_{k'})}$

Meaning: $\hat{z}_i - \mu_k$

Page: $\frac{1}{2} \frac{1 + \hat{z}_i - \mu_k}{\sum_{k'=1}^K (1 + \hat{z}_i - \mu_{k'})}$

Notes: $\hat{z}_i - \mu_{k'}$

Field 6: $\frac{1}{2} \frac{1 + \hat{z}_i - \mu_k}{\sum_{k'=1}^K (1 + \hat{z}_i - \mu_{k'})}$

Field 7: Student's t-distribution-based soft assignment

Field 8: p. 7

Field 9: Enables probabilistic clustering; centroid μ_k warm-started by k-means [Paper: PDF p. 7]

ID: Eq. 17

Formula: $\mathcal{L}_{\text{OmicSync}} = \lambda_r \mathcal{L}_{\text{recon}} + \lambda_c(t) \mathcal{L}_{\text{contrast}} + \lambda_k \mathcal{L}_{\text{cluster}} + \lambda_b \mathcal{L}_{\text{celltype}} + \lambda_p \mathcal{L}_{\text{impute}} + \lambda_u \mathcal{L}_{\text{unc}}$

Meaning: End-to-end training objective

Page: p. 7

Notes: Multi-task loss balancing reconstruction, contrastive, clustering, auxiliary, imputation, uncertainty terms [Paper: PDF p. 7]

ID: Eq. 18

Formula: $\text{GR}_i = \frac{|\text{M}_i \cap \text{J}_i|}{|\text{M}_i|}$

Meaning: Grounding rate: fraction of supplied marker names (M_i) appearing in justification (J_i)

Page: p. 9

Notes: Primary faithfulness metric; highest weight ($w_1 = 0.5$) in R_i [Eq. 20, Paper: PDF p. 9]

ID: Eq. 19

Formula: $\text{S}_i \sim \text{Categorical}(q_i)$

Meaning: Sampling candidate domain label S_i from ClusteringHead's soft assignment

Page: p. 9

Notes: Enables REINFORCE update in OmicSync-R; evidence dictionary conditioned on S_i [Paper: PDF p. 9]

ID: Eq. 20

Formula: $\text{R}_i = w_1 \text{GR}_i + w_2 \text{CA}_i + w_3 \text{SC}_i \in [0,1]$

Meaning: Composite reasoning-quality reward for spot i

Page: p. 9

Notes: $w_1=0.5$, $w_2=0.3$, $w_3=0.2$; used as REINFORCE reward [Paper: PDF p. 9]

ID: Eq. 23

Formula: $\mathcal{L}_{\text{reinforce}} = -\frac{1}{|\text{S}_R|} \sum_{i \in \text{S}_R} \text{sg}(\text{R}_i - b_t) \log q_{i,a_i}$

Meaning: REINFORCE loss term for OmicSync-R

Page: p. 10

Notes: Stop-gradient $\text{sg}(\cdot)$ treats R_i and baseline b_t as constants; updates q_i without LLM gradients [Paper: PDF p. 10]

ID: Eq. 24

Formula: $\mathcal{L}_{\text{OmicSync-R}} = \mathcal{L}_{\text{OmicSync}} + \lambda_R \mathcal{L}_{\text{reinforce}}$

Meaning: Extended training objective for OmicSync-R

Page: p. 10

Notes: $\lambda_R = 0.02$; REINFORCE active only at reasoning-update epochs [Paper: PDF p. 10]

10 实验设计与证据链

Experiment / Claim tested / Comparison and conditions / Result / Supported conclusion / Unsupported stronger conclusion / Source

Experiment: Table 1 clustering rank

Claim tested: OmicSync achieves state-of-the-art clustering performance across four CytAssist FFPE datasets

Comparison and conditions: Compared against GROVER, MISO, SpatialGlue, COSMOS on ARI, NMI, FMI, SiLC, AMI, Jaccard, CHI, Purity, DBI; best result over $\{6, \dots, 10\}$ reported; pseudo-reference labels from GROVER used for external evaluation [Paper: PDF p. 11]

Result: Best average rank on Human Tonsil (1.44), Glioblastoma (1.78), Tonsil Add-on (1.22); second-best on Human Breast Cancer (2.33); best ARI on all four datasets [Paper: PDF p. 12]

Supported conclusion: OmicSync's architecture (KAN-GCN, CrossModalTransformer, UncertaintyMoE, adaptive nhops) yields superior domain discovery on these FFPE benchmarks

Unsupported stronger conclusion: That OmicSync generalizes to non-FFPE or non-10x platforms (not tested)

Source: Table 1 [Paper: PDF p. 12]

Experiment: Figure 2 & Table 2

Claim tested: Task B (CellTypeHead) provides meaningful pseudo-cell-type regularisation

Comparison and conditions: CellTypeHead trained on Leiden-derived RNA pseudo-labels (70% used); prediction maps visualised qualitatively; no external ground-truth available [Paper: PDF p. 13]

Result: Maps show locally structured patterns: Glioblastoma -> large coherent regions; Tonsil -> fine-grained mixed domains [Fig. 2, Table 2]

Supported conclusion: Auxiliary pseudo-label supervision encourages latent space to retain local cell-type organisation, supporting its role as regulariser

Unsupported stronger conclusion: That CellTypeHead achieves high accuracy on true cell-type annotation (not evaluated; explicitly stated as non-benchmark) [Paper: PDF p. 13]

Source: Fig. 2 & Table 2 [Paper: PDF p. 13-14]

Experiment: Table 3 & Figure 3A

Claim tested: Stepwise reasoning strategy achieves highest joint faithfulness

Comparison and conditions: Five strategies (Standard, Stepwise, Counterfactual, Contrastive, Uncertainty) evaluated on same 40 spots (10/dataset); GR/CA/SC computed automatically [Paper: PDF p. 13]

Result: Stepwise: GR=1.00, CA=1.00, SC=0.975; Uncertainty: GR=0.074, CA=1.00 (trade-off) [Table 3, Fig. 3A]

Supported conclusion: Structured five-stage prompting forces explicit referencing of all evidence types, maximising faithfulness

Unsupported stronger conclusion: That Stepwise is universally optimal across all future datasets or tasks (only tested on 4 FFPE datasets)

Source: Table 3 & Figure 3A [Paper: PDF p. 13, 21]

Experiment: Table 5 reliability audit

Claim tested: High-confidence spots exhibit lower uncertainty and higher spatial homogeneity

Comparison and conditions: Three-tier confidence groups (High ≥ 0.35 , Medium, Low < 0.20) defined on 40 explained spots; avg. $\$u_i$ and neighbourhood homogeneity computed [Paper: PDF p. 15]

Result: High-confidence: avg. $\$u_i=0.034$, homogeneity=75.6%; Low-confidence: avg. $\$u_i=0.111$ (3.3x higher), homogeneity=60.0% [Table 5]

Supported conclusion: Numerical reliability signals ($\$c_i$, $\$u_i$) reflect meaningful variation in assignment stability and local spatial support

Unsupported stronger conclusion: That this correlation implies causation (e.g., lowering $\$u_i$ directly causes higher homogeneity)

Source: Table 5 [Paper: PDF p. 16]

Experiment: Table 6 & 7 OmicSync-R

Claim tested: Reasoning-quality reward improves clustering metrics on Human Breast Cancer

Comparison and conditions: OmicSync-R trained with $\lambda_R=0.02$, $N_R=25$, S_R

Result: S_R

Supported conclusion: $=10$; compared to base OmicSync and GROVER at $k=10$; reward trajectory tracked over 22 updates [Paper: PDF p. 16-17]

Unsupported stronger conclusion: ARI improves from 45.73 -> 46.72 (+0.99); 8/9 metrics improve (e.g., Jaccard +3.08, DBI -13.46); NMI declines -1.90 [Table 7]; GR ≈ 1.00 , CA peaks at 0.775 [Table 6]

Source: REINFORCE with automated $\$R_i$ provides usable auxiliary signal for reasoning-guided training on this dataset

Field 8: That OmicSync-R's benefit is k -agnostic (it is k -sensitive: benefit concentrated at $k=10$) [Paper: PDF p. 17]

Field 9: Table 6 & 7 [Paper: PDF p. 16-17]

11 对结论的正确理解

- OmicSync 的“best average rank” (e.g., 1.44 on Human Tonsil) is computed across nine metrics (ARI, NMI, FMI, SilC, AMI, Jaccard, CHI, Purity, DBI), not a single metric; bold/underline in Table 1 denote per-metric best/second-best, but rank aggregates across all [Paper: PDF p. 12].
- Task B’s “pseudo-cell-type prediction maps” are qualitative only, trained on RNA-derived Leiden pseudo-labels, and explicitly not evaluated as a supervised cell-type classification benchmark due to lack of ground-truth [Paper: PDF p. 13].
- The “Stepwise” strategy’s perfect GR=1.00 and CA=1.00 does not imply universal superiority: it sacrifices no metrics here, but the Uncertainty strategy deliberately trades GR for CA, reflecting design intent, not failure [Fig. 3A, Table 3, Paper: PDF p. 13, 21].
- OmicSync-R’s ARI improvement (+0.99) is statistically modest and observed only at $k=10$; it degrades at $k=6-9$, and NMI decreases, indicating a nuanced, not monolithic, gain [Table 7, Paper: PDF p. 17].
- “Reliability-aware” means the framework outputs three distinct, model-derived signals (c_i , u_i , $\bar{g}_i$) and uses them for reasoning, not that it guarantees correctness-e.g., low u_i reflects routing stability, not biological truth [Paper: PDF p. 3-4, 6].

12 作者明确承认的限制

Limitation / Specific manifestation / Future direction proposed by authors / Source

Limitation: Post-hoc reasoning in base OmicSync

Specific manifestation: Task C operates after training and does not back-propagate into clustering objective; explains but does not optimise the partition

Future direction proposed by authors: Addressed by OmicSync-R via REINFORCE, but OmicSync-R itself has limitations (see below) [Paper: PDF p. 18]

Source: Discussion: “Base OmicSync’s Task C operates after model training and does not back-propagate into the clustering objective; it explains rather than optimises the partition” [Paper: PDF p. 18]

Limitation: OmicSync-R resource intensity

Specific manifestation: Requires repeated LLM queries (220 total for Human Breast Cancer) and reward computation during training; more resource-intensive than post-hoc explanation

Future direction proposed by authors: Explore amortised reward models, cached reasoning evaluations, and smaller verifier models to reduce cost [Paper: PDF p. 18]

Source: Discussion: “Because the iterative REINFORCE loop requires repeated calls to the reasoning module, OmicSync-R is more resource-intensive… Future work will also explore amortised reward models, cached reasoning evaluations, and smaller verifier models” [Paper: PDF p. 18]

Limitation: OmicSync-R k -sensitivity

Specific manifestation: Benefit concentrated at $k=10$; ARI drops substantially at $k=6-9$, suggesting poor generalisation across cluster numbers

Future direction proposed by authors: Investigate reward annealing or multi- k training to reduce k -sensitivity [Paper: PDF p. 18]

Source: Discussion: “The benefit of OmicSync-R is concentrated at $k = 10$ … The interaction between the REINFORCE reward and centroid selection therefore warrants further investigation” [Paper: PDF p. 18]

Limitation: Limited reward scope

Specific manifestation: Reward R_i based only on three automatically computable metrics (GR/CA/SC); spatial consistency (SC) remains unstable and hard to optimise with spot-level rewards

Future direction proposed by authors: Investigate graph-level or neighbourhood-aware reward

formulations to improve SC [Paper: PDF p. 18]

Source: Discussion: “Improving this component may require a graph-level or neighbourhood-aware reward formulation” [Paper: PDF p. 18]

Limitation: Task B pseudo-label limitation

Specific manifestation: CellTypeHead trained on RNA-derived Leiden pseudo-labels, not external ground-truth; analysis evaluates regularisation benefit, not classification accuracy

Future direction proposed by authors: Not specified; implied need for multi-modal ground-truth annotations [Paper: PDF p. 13, 18]

Source: Discussion: “Task B pseudo-labels are RNA-derived, so the reported analysis evaluates the regularisation benefit… rather than external classification accuracy” [Paper: PDF p. 18]

13 批判性分析

[Analysis] Observation / Potential issue or alternative explanation / Why it matters / How to test it / Basis

[Analysis] Observation: OmicSync-R’s REINFORCE update uses $a_i \sim \text{Categorical}(q_i)$, but the evidence dictionary is conditioned on a_i , meaning the LLM sees only evidence supporting the sampled domain, not the runner-up or full distribution

Potential issue or alternative explanation: This creates a confirmation bias: the LLM is never asked to explain why the runner-up domain was rejected, potentially inflating GR/CA/SC by avoiding counter-evidence. The reward thus measures coherence with a cherry-picked view, not holistic faithfulness

Why it matters: If R_i is inflated, the REINFORCE signal may misguide the model toward overconfident, narrow representations, harming generalisation

How to test it: Compare OmicSync-R against a variant where evidence dictionary includes both top-2 domains and their margins, or where R_i is averaged over multiple a_i samples per spot

Basis: Section 6.1 states evidence dictionary includes “the predicted domain $\hat{k}_i$ and assignment confidence c_i ” and “the runner-up domain $\hat{k}^{(2)}_i$ ” [Paper: PDF p. 8], but Section 7.1 specifies “an evidence dictionary conditioned on the sampled domain a_i ” [Paper: PDF p. 9], implying conditioning excludes runner-up when $a_i \neq \hat{k}_i$

[Analysis] Observation: The “adaptive nhops” mechanism sets $n_{\text{hops}}=2$ for homogeneous tissue (avg. RNA neighbour similarity >0.6) and $n_{\text{hops}}=1$ for heterogeneous, but this threshold (0.6) is arbitrary and not validated across datasets

Potential issue or alternative explanation: Threshold choice may misclassify datasets: e.g., if Human Breast Cancer’s avg. similarity is 0.59, it gets $n_{\text{hops}}=1$, but a value of 0.61 would flip it to $n_{\text{hops}}=2$, potentially harming performance. No ablation shows robustness to this threshold

Why it matters: This undermines the claim of “adaptive” smoothing; it may be dataset-specific tuning masquerading as adaptation, reducing generalisability to unseen tissues

How to test it: Perform ablation study varying the similarity threshold (e.g., 0.5, 0.55, 0.6, 0.65) and measure impact on ARI/SiC trade-off across all four datasets

Basis: Section 4.8: “Homogeneous tissue, defined by an average neighbor similarity greater than 0.6… uses $n_{\text{hops}}=2$ ” [Paper: PDF p. 7]; no sensitivity analysis provided

[Analysis] Observation: Table 7 shows OmicSync-R improves 8/9 metrics but degrades NMI (-1.90), yet the paper highlights ARI gain without contextualising NMI loss

Potential issue or alternative explanation: NMI penalises cluster size imbalance more harshly than ARI; degradation suggests OmicSync-R may produce clusters with more unequal sizes, potentially harming biological interpretability (e.g., one dominant domain swamping others). This trade-off is unexamined

Why it matters: Optimising for ARI+reward may distort cluster geometry in ways detrimental to downstream biology, even if metrics improve. Ignoring NMI loss risks overclaiming benefit

How to test it: Report cluster size distributions for OmicSync vs. OmicSync-R; correlate NMI loss with biological plausibility of domains (e.g., via known marker enrichment)

Basis: Table 7: “NMI declines modestly from 54.10 to 52.20 (-1.90)” [Paper: PDF p. 17]; no discussion of implications

[Analysis] Observation: The reasoning module uses Llama-3.3-70B via Groq API, but Groq's hardware acceleration may introduce non-determinism or hidden biases in token generation
Potential issue or alternative explanation: If Groq's inference stack alters LLM behaviour (e.g., via speculative decoding), the faithfulness metrics (GR/CA/SC) may reflect API quirks, not model capability. This threatens reproducibility, especially for REINFORCE where reward depends on LLM output

Why it matters: Non-reproducible LLM behaviour makes OmicSync-R's training loop fragile; results may not transfer to other LLMs or inference setups, limiting method adoption

How to test it: Replicate reasoning on same prompts using open-weight Llama-3.3-70B on standard GPU (e.g., H100) and compare GR/CA/SC distributions

Basis: Section 6.3: "Justifications are generated by Llama-3.3-70B accessed through the Groq inference API" [Paper: PDF p. 9]; no control for API-specific effects

- Reliability in spatial clustering must be multi-dimensional: Single metrics like ARI are insufficient; OmicSync demonstrates that assignment confidence ($\$c_i\$$), epistemic uncertainty ($\$u_i\$$), and modality attribution ($\bar{\$g_i\$}$) are orthogonal, complementary signals necessary for responsible interpretation [Paper: PDF p. 3-4, 15].
- MC-Dropout for routing uncertainty is actionable: By applying dropout to the MoE gating network and aggregating variance across samples, OmicSync extracts $\$u_i\$$ as a scalar proxy for routing stability—a practical, lightweight Bayesian approximation usable in production [Paper: PDF p. 6-7, Eq. 11-13].
- Evidence-constrained prompting works: Restricting LLM input to a structured dictionary of model-derived signals (no free-text context) and forbidding external knowledge yields high GR (up to 1.00), proving that faithfulness can be engineered via input design, not just model size [Paper: PDF p. 8-9, Table 3].
- REINFORCE enables non-differentiable alignment: OmicSync-R validates that discrete, automated rewards (GR/CA/SC) can guide latent space learning without LLM gradients, offering a template for integrating symbolic AI (LLM reasoning) with subsymbolic AI (neural clustering) [Paper: PDF p. 9-10, Eq. 23-24].
- Adaptive contrastive learning is dataset-aware: The nhops mechanism-switching between $\$n_{\text{hops}}=1\$$ and $\$2\$$ based on RNA neighbour similarity—provides a simple, effective way to tune spatial smoothing per dataset, resolving the ARI/SiIC trade-off without manual intervention [Paper: PDF p. 7].

- single-cell foundation models: OmicSync's use of UNI for histology [Paper: PDF p. 5] and KAN-GCN for RNA/ADT [Paper: PDF p. 6] aligns with foundation model principles (pretrained encoders, modality-specific processing), but extends them to spatially resolved multi-omics with explicit uncertainty modeling—unlike scFoundation or scGPT which focus on dissociated cells [Paper: PDF p. 5, 6].
- spatial transcriptomics: OmicSync directly addresses the “why” gap in spatial clustering tools (e.g., BayesSpace [3], GraphST [11]) by adding per-spot explanations, moving beyond visualisation (e.g., attention maps) to natural language auditing [Paper: PDF p. 1-2, 11].
- graph neural networks: Builds on GROVER's KAN-GCN backbone [5] but adds critical layers: spatial position encoding [Eq. 7], UncertaintyMoE [Eq. 11-13], and reasoning-coupled heads—transforming a static GNN into a reliability-aware, self-auditing system [Paper: PDF p. 3, 6].
- multi-omics: Unlike MISO [6] (multi-scale) or SpatialGlue [7] (cross-attention),

OmicSync fuses modalities via uncertainty-weighted MoE, making modality contribution explicit and quantifiable ($\bar{g}_i$, u_i), enabling interpretation of which modality drives each assignment [Paper: PDF p. 4, 6-7].

- biomedical AI: The five-strategy reasoning taxonomy (Stepwise/Counterfactual/etc.) provides a clinical reasoning scaffold, mirroring diagnostic workflows-e.g., Stepwise's five stages parallel "evidence $\rightarrow$ modality $\rightarrow$ spatial context $\rightarrow$ uncertainty $\rightarrow$ conclusion"-making outputs more accessible to domain experts [Paper: PDF p. 8].
- perturbation prediction & cell state representation: While not directly predicting perturbations, OmicSync's uncertainty-aware routing and confidence calibration could inform perturbation robustness (e.g., high u_i spots may be more sensitive); its shared latent Z is a candidate cell-state representation, though not explicitly validated for dynamics [Paper: PDF p. 4, 7].
- cross-modal alignment: OmicSync's CrossModalTransformer [Eq. 9] and UncertaintyMoE perform learned, uncertainty-gated alignment, contrasting with rigid concatenation (COSMOS [8]) or fixed-weight fusion-offering a more principled approach to multi-modal integration in noisy biomedical data [Paper: PDF p. 6-7].
- Weak connection/methodology connection: The paper does not address perturbation prediction, cell state dynamics, or cross-modal alignment as primary goals; connections are methodological (e.g., uncertainty-aware fusion could extend to perturbation settings) but not empirically demonstrated.

16 研究想法

- name: Uncertainty-Calibrated Perturbation Sensitivity Scoring

originating limitation/observation: OmicSync-R's u_i quantifies routing instability but is not linked to perturbation response; Table 5 shows high-confidence spots have lower u_i and higher spatial homogeneity, suggesting u_i may proxy for local robustness [Paper: PDF p. 15-16].

core hypothesis: Epistemic routing uncertainty u_i correlates with spot-level sensitivity to molecular perturbations (e.g., gene knockdown, drug treatment); low- u_i spots exhibit stable domain assignments under perturbation, while high- u_i spots shift domains.

delta from paper: Extends u_i from a static reliability signal to a dynamic perturbation sensitivity predictor, requiring perturbation data and causal evaluation.

initial method: Apply in silico perturbations (e.g., mask top RNA genes per spot) to Human Breast Cancer data; compute delta in u_i and domain assignment shift; train a regressor mapping u_i to perturbation sensitivity score.

validation: Correlate predicted sensitivity with experimental perturbation outcomes (e.g., from CROP-seq or spatial drug screens); assess if low- u_i spots are enriched for essential genes.

failure modes: u_i may reflect technical noise (e.g., low-coverage spots) rather than biological sensitivity; perturbation effects may be non-linear and not captured by single u_i .

innovation status: unverified

- name: Graph-Aware REINFORCE for Spatial Consistency

originating limitation/observation: OmicSync-R's spot-level REINFORCE fails to improve spatial consistency (SC), which declines late in training; authors propose

“graph-level or neighbourhood-aware reward formulations” [Paper: PDF p. 18].

core hypothesis: A reward computed over spatial neighbourhoods (e.g., agreement between a spot’s assignment and its 5-nearest neighbours’ assignments) will better optimise SC than spot-level SR_i , as SC inherently measures spatial coherence.

delta from paper: Replaces spot-level SR_i with a neighbourhood-aggregated reward $SR_i^{\text{graph}} = \frac{1}{5} \sum_{j \in \text{neighbours}(i)} \mathbb{I}[\hat{k}_i = \hat{k}_j]$, computed during REINFORCE updates.

initial method: At each reasoning-update epoch, for each $i \in S_R$, compute SR_i^{graph} using current $\hat{k}_i$; replace SR_i in Eq. 20 with SR_i^{graph} ; retrain OmicSync-R on Human Breast Cancer.

validation: Compare SC trajectory (Table 6) and final SC value against original OmicSync-R; check if spatial homogeneity (Table 5) improves in low-confidence group.

failure modes: Neighbourhood agreement may reinforce spatial smoothing at the cost of biological boundaries (e.g., tumour-stroma); SR_i^{graph} is binary and less informative than GR/CA.

innovation status: unverified

- name: Multi-Modal Verifier for Faithfulness Compression

originating limitation/observation: OmicSync-R’s reliance on Groq-hosted Llama-3.3-70B is resource-intensive and non-reproducible [Paper: PDF p. 9, 18]; authors seek “smaller verifier models” [Paper: PDF p. 18].

core hypothesis: A lightweight, task-specific verifier model (e.g., 100M-param RoBERTa) fine-tuned to score GR/CA/SC from evidence-justification pairs can replace Llama-3.3-70B in the REINFORCE loop, reducing cost while preserving faithfulness signal fidelity.

delta from paper: Substitutes the black-box LLM with a trainable, compact verifier, enabling end-to-end differentiability and reproducibility.

initial method: Collect 10k evidence-justification pairs from OmicSync’s reasoning module; train RoBERTa-base to predict GR/CA/SC as regression targets; integrate verifier output as SR_i in Eq. 20.

validation: Compare verifier’s GR/CA/SC scores vs. Llama-3.3-70B on held-out test set (Pearson r); measure OmicSync-R’s ARI gain and training time vs. original.

failure modes: Verifier may learn spurious correlations (e.g., length heuristics) rather than true faithfulness; distillation loss may degrade reward signal quality.

innovation status: unverified
