01 基本信息

Field	Value	Source
Title	Correlation-Guided Flow Matching with Annealed Masking for Spatial Transcriptomics Generation	[Paper] [Paper: PDF p. 1]
Authors	Yupei Zhang, Hao Chen, Li Pan, Chao Li, Xiaohan Xing	[Paper] [Paper: PDF p. 1]
Venue	arXiv preprint (cs.LG)	[Paper] [Paper: PDF p. 1]
Publication date	2026-09-01	[Paper] [Paper: PDF p. 1]
Core task	Histology-to-ST prediction (spatial transcriptomics generation from H&E images)	[Paper] [Paper: PDF p. 1–2]
Method name	CorrFlow	[Paper] [Paper: PDF p. 1–2]
Key technique 1	Annealed masked flow matching (Annealed-MFM)	[Paper] [Paper: PDF p. 2–5]
Key technique 2	Gene graph-regularized optimization (STRING + WGCNA fusion)	[Paper] [Paper: PDF p. 2–6]
Primary evaluation metric	PCC (Pearson correlation coefficient) and HPCC (Hallmark-Gene PCC) on HMMVG-50 genes	[Paper] [Paper: PDF p. 7–8]
Benchmark datasets	HEST-1K (10 cancer/tissue types), STImage-1K4M (Brain, Breast)	[Paper] [Paper: PDF p. 7, 18]
Baseline model	STFlow (conditional flow matching)	[Paper] [Paper: PDF p. 7]
Code/data availability	Not stated in text; no URL, GitHub, or repository link provided	Not assessable from supplied material

02 一句话总结

本文提出 CorrFlow，一种面向空间转录组（ST）生成的条件流匹配框架，通过**渐进式基因掩码（annealed masking）**和**基因图正则化（gene graph regularization）**两大机制，显式建模基因间依赖关系，解决现有生成模型将基因视为独立预测目标、忽略生物学共表达结构的根本缺陷。该方法在10个 HEST-1K 数据集上系统性超越 STFlow 等基线，在 PCC 和 HPCC 上取得最优平均性能，尤其提升通路级表达协调性；其设计直击单细

胞与空间多组学中“基因非独立性”这一核心建模盲区，为跨模态对齐与 perturbation prediction 提供可解释的依赖建模范式。

03 研究问题

论文聚焦于：如何在 histology-to-ST 生成任务中，使生成模型不再将 G 维基因表达向量 $x_1 \in \mathbb{R}^G$ 视为 G 个独立标量输出，而是建模其内在的、受调控网络与通路活动驱动 **的联合分布 $p(x_1 | z, q)$** ？作者指出，该问题并非技术实现细节，而是由标准流匹配（CFM）和扩散（diffusion）的目标函数结构性分解所导致——其损失函数天然按基因维度可分（ $L = \sum_g L^{(g)}$ ），因此不奖励、也不要求模型学习跨基因推理能力 [Paper] [Paper: PDF p. 4–5]。这导致模型虽有共享骨干网络，却缺乏优化动力去捕捉如 KRT7 与其它上皮标志物间的协同表达模式 [Paper] [Paper: PDF p. 9]。研究问题本质是：**如何重构训练信号与约束，使模型的最优解必须依赖于基因间条件依赖？**

04 研究背景与发展路径

早期工作（ST-Net）采用确定性回归，无法建模表达不确定性；检索法（BLEEP）依赖参考集覆盖度；近期生成范式（Stem、STFlow）虽引入随机性，但仍未突破“per-gene marginal estimation”范式 [Paper] [Paper: PDF p. 2–3]。关键转折点在于作者识别出：**现有生成目标的数学结构（Proposition 1）决定了其无法内生地鼓励跨基因建模** [Paper] [Paper: PDF p. 4]。因此发展路径不是堆叠更强 backbone，而是从**目标函数层面重构学习信号**：先用掩码打破输入-输出维度一一对应（Section 3.2），再用图正则化施加生物学先验约束（Section 3.3）。该路径区别于单纯引入 GNN 编码器（如 Zeng et al. 2022 [38]）或图注意力（Shi et al. 2025 [25]），而是将图结构嵌入生成动力学（flow dynamics）与输出空间（expression space）双重层面。

05 论文识别的核心痛点

Pain point	Manifestation	Cause or author explanation	Evidence from the paper		
Per-gene decomposition of training objective	Models achieve high PCC on some genes but fail on highly correlated ones (e.g., x_3^1 in Fig. 1); uneven gene-level performance	Standard CFM/diffusion loss decomposes as sum over genes (Eq. 3), so optimal predictor for gene g depends only on marginal $p(x_{g_1} \setminus$	$x_t, t, c)$, not joint $p(x_1 \setminus$	c) [Paper] [Paper: PDF p. 4–5]	[Paper] [Paper: PDF p. 4] Proposition 1 & proof; [Paper] [Paper: PDF p. 2] Fig. 1 caption; [Paper] [Paper: PDF p. 5] “cross-gene coordination is therefore unidentifiable under the standard objective”

Pain point	Manifestation	Cause or author explanation	Evidence from the paper
Lack of biological coherence in generated expression	Predictions may be numerically accurate per gene but violate known co-expression modules or pathway activity	No explicit mechanism to enforce that functionally related genes (e.g., STRING-linked) or co-expressed genes (e.g., WGCNA modules) have consistent predicted expression patterns	[Paper] [Paper: PDF p. 1] Abstract: “overlook the intrinsic gene-gene interactions... limits their ability to preserve biologically meaningful co-expression patterns” ; [Paper] [Paper: PDF p. 6] “finite model capacity and noisy gradients can still lead to predictions that violate known co-expression structures”
Shortcut reconstruction near $t=1$	Network copies near-target values from x_t instead of learning transport dynamics	As $t \rightarrow 1$, $x_t \rightarrow x_1$, making endpoint prediction trivial without additional pressure	[Paper] [Paper: PDF p. 5] “Conditional flow matching suffers from a practical shortcut issue... allowing the network to shortcut by copying near-target values”

06 核心思想

论文的核心思想是：**要让模型学会“基因依赖”，不能只靠更大模型或更多数据，而必须让“依赖建模”成为其最优解的必要条件。**这通过两个互补且可证明有效的机制实现：（1）**Annealed-MFM** 将标准 CFM 的输入 x_t 替换为掩码版 $\tilde{x}_t$ ，且掩码比例 $p(t)$ 随 t 线性增长（Eq. 8）；这使得当模型最易走捷径（ t 接近 1）时，输入信息最匮乏，被迫从剩余基因中推断被掩码基因，从而将最优解从 $v^g = E[x^g_1 \mid x_t, t, c]$ 强制升级为 $v^g = E[x^g_1 \mid x^{(O)}_t, t, c]$ （Proposition 2），即必须利用观测基因集合 O 的联合条件分布；（2）**Gene Graph Regularization** 不满足于仅靠数据驱动学习依赖，而是融合外部功能先验（STRING）与数据驱动共表达（WGCNA）构建基因亲和图 S （Eq. 9），再通过 Huber 局部平滑项（Eq. 11）和图拉普拉斯全局平滑项（Eq. 12）双重约束输出 $\hat{x}_1$ ，使预测表达在图结构上既局部一致又全局平滑，直接锚定生物学合理性。

07 方法总览

CorrFlow 是一个端到端的 conditional flow matching 框架，以 histology features z 和 spatial coordinates q 为条件，学习从噪声先验 x_0 （ZINB）到目标 ST 表达 x_1 的连续传输场。其方法总览为：**给定线性插值 $xt =$**

$(1-t)x_0 + t x_1$ (Eq. 1), 模型接收掩码输入 $\tilde{x}_t$ (Eq. 5), 经 spatial-transformer denoiser 预测终点 x_1 , 并同时优化两项损失: (i) 掩码流匹配损失 LMFM (Eq. 6), 强制联合条件建模; (ii) 基因图正则化损失 $L_{\text{graph}} = \rho L_{\text{local}} + \lambda L_{\text{global}}$ (Eq. 12, 16), 强制生物学一致性。整个流程在 Algorithm 1 中完整呈现 [Paper] [Paper: PDF p. 14], 所有模块均服务于一个统一目标: 使模型的最优参数 θ^* 必须编码基因间依赖知识, 否则无法最小化联合损失。

08 核心模块拆解

Module	Function	Why needed	Input and output	Supporting evidence	Known or expected effect of removal
Annealed Masking Schedule	Applies timestep-dependent Bernoulli mask to input x_t , with $p(t) = p_{\text{max}} \cdot t$ (Eq. 8); replaces masked entries with learnable token m (Eq. 5)	To break per-gene decomposition (Proposition 1) and force joint conditional modeling (Proposition 2); annealing prevents shortcut at $t \approx 1$	Input: x_t, t ; Output: $\tilde{x}_t \in \mathbb{R}^G$	[Paper] [Paper: PDF p. 5] “suppress this by coupling the masking ratio to the timestep” ; [Paper] [Paper: PDF p. 5] Proposition 2 proof; [Paper] [Paper: PDF p. 8] Table 2: w/o masking $\rightarrow$ PCC $\downarrow 0.004$	Ablation shows PCC drops to 0.609 (vs. 0.613), confirming its role in preventing shortcut and enabling dependency-aware inference [Paper] [Paper: PDF p. 8]
Gene Affinity Graph Construction	Fuses STRING prior $S^{(s)}$ and WGCNA-derived co-expression $S^{(w)}$ via weighted average $S = \alpha S^{(s)} + (1-\alpha)S^{(w)}$ (Eq. 9), then computes normalized adjacency A and Laplacian L (Eq. 10)	To inject structured biological knowledge into the optimization, guiding predictions toward coherent co-expression patterns beyond what data alone may suggest	Input: STRING database, training expression data; Output: $S, A, L \in \mathbb{R}^{G \times G}$	[Paper] [Paper: PDF p. 6] “We construct a gene affinity graph from two complementary sources” ; [Paper] [Paper: PDF p. 8] Table 2: w/o Lgraph $\rightarrow$ PCC $\downarrow 0.008$, larger drop than w/o masking	Removal causes largest PCC drop (0.605), indicating graph constraint is critical for stabilizing predictions under dependency structure [Paper] [Paper: PDF p. 8]
Local Graph Constraint (Llocal)	Penalizes discrepancy $\Delta_{n,ij} = z_i - z_j$ between z-scored predictions of connected genes $(i,j) \in E$ using Huber loss weighted by S_{ij} (Eq. 11)	To enforce pairwise consistency among functionally related genes, robust to outliers on weak edges	Input: $\hat{x}_1, n, \mu_i, \sigma_i, S$; Output: scalar Llocal	[Paper] [Paper: PDF p. 6] “Connected genes in G should produce similar predictions” ; [Paper] [Paper: PDF p. 8] Table 2: w/o Llocal $\rightarrow$ PCC $\downarrow 0.008$	Ablation shows identical PCC drop as w/o Lgraph, suggesting Llocal carries most of the graph’s constraining power [Paper] [Paper: PDF p. 8]

Module	Function	Why needed	Input and output	Supporting evidence	Known or expected effect of removal
Global Graph Constraint (Lglobal)	Penalizes $\hat{x}_{1,n}^T L \hat{x}_{1,n}$ (Eq. 12), encouraging output to align with low-frequency eigenmodes of G	To capture graph-wide co-expression modules that local pairwise terms miss, suppressing rapid oscillations across the gene graph	Input: $\hat{x}_{1,n}, L$; Output: scalar Lglobal	[Paper] [Paper: PDF p. 6–7] “Llocal operates on individual edges and cannot capture graph-wide patterns” ; [Paper] [Paper: PDF p. 8] Table 2: w/o Lglobal $\rightarrow$ PCC $\downarrow$ 0.004 (same as w/o masking)	Removal has same impact as w/o masking, indicating it provides complementary, non-redundant global smoothing [Paper] [Paper: PDF p. 8]
Learnable Mask Token	Replaces masked genes with trainable vector $m \in \mathbb{R}^G$, initialized to zero	To avoid train-inference magnitude mismatch caused by fixed-zero masking (analogous to dropout scaling problem)	Input: None (parameter); Output: m used in Eq. 5	[Paper] [Paper: PDF p. 5] “introduce a learnable mask token... to mitigate this issue” ; [Paper] [Paper: PDF p. 5] “the network jointly learns what to substitute for missing genes”	Not ablated separately, but its design rationale addresses a concrete optimization instability, implying removal would harm convergence [Paper] [Paper: PDF p. 5]

09 关键公式与符号

论文未提供单一主导性“模型公式”，而是定义了一套相互支撑的**目标函数组件与图结构算子**。关键符号与公式如下（全部可核验）：

- **Flow interpolation:** $x_t = (1 - t) x_0 + t x_1$ (Eq. 1)
- **Masked input:** $\tilde{x}_{t,g} = \{ m_g \text{ if } g \in M; x_{t,g} \text{ if } g \in O \}$ (Eq. 5), where M is mask set, O is observed set
- **Annealed masking ratio:** $p(t) = p_{\max} \cdot t$ (Eq. 8)
- **Gene affinity fusion:** $S = \alpha S^{(s)} + (1 - \alpha) S^{(w)}$ (Eq. 9), with $S^{(s)}$ from STRING, $S^{(w)}$ from WGCNA
- **Normalized adjacency & Laplacian:** $A = D^{-1/2} S D^{-1/2}$, $L = I - A$ (Eq. 10)
- **Local graph loss:** $L_{\text{local}} = (1/N) \sum_n \sum_{(i,j) \in E} w_{ij} \text{Huber}\beta(\Delta n_{ij}), w_{ij} \propto S_{ij}$ (Eq. 11)
- **Global graph loss:** $L_{\text{global}} = (1/N) \sum_n \hat{x}_{1,n}^T L \hat{x}_{1,n}$ (Eq. 12)
- **Overall objective:** $L = \text{LMFM} + L_{\text{graph}} = \text{LMFM} + \rho L_{\text{local}} + \lambda L_{\text{global}}$ (Eq. 16)
- **PCC per gene:** $r_g = \text{cov}(\tilde{y}_{:,g}, y_{:,g}) / (\sigma(\tilde{y}_{:,g}) \sigma(y_{:,g}))$ (Eq. 17)
- **HPCC:** $\text{HPCC} = (1/|K|) \sum_k (1/|P_k \cap G|) \sum_{g \in P_k \cap G} r_g$ (Eq. 13), where $K = \{k : |P_k \cap G| \geq 5\}$
- **GGC-Pearson:** $\text{corr}(\text{vec}\Delta(\hat{C}), \text{vec}\Delta(C))$ (Eq. 20), measuring agreement of gene-gene correlation matrices
- **MSE-Mean:** $(1/G) \sum_g \text{MSE}_g$, $\text{MSE}_g = (1/N) \sum_i (\tilde{y}_{ig} - y_{ig})^2$ (Eq. 21–22)

10 实验设计与证据链

Experiment	Claim tested	Comparison and conditions	Result	Supported conclusion	Unsupported stronger conclusion	Source
Main benchmark (Table 1)	CorrFlow > STFlow on average PCC/HPCC across 10 HEST-1K datasets	CorrFlow vs. STFlow, TRIPLEX, BLEEP, etc., on HMMVG-50, patient-stratified CV	CorrFlow: PCC=0.613, HPCC=0.628; STFlow: PCC=0.600, HPCC=0.613	CorrFlow achieves state-of-the-art on this benchmark; gain on HPCC > PCC suggests improved pathway-level coherence	That CorrFlow generalizes to <i>all</i> ST tasks or clinical settings; no external validation performed	[Paper] [Paper: PDF p. 8] Table 1
Ablation study (Table 2)	Each proposed component contributes positively	Full CorrFlow vs. variants removing masking, Lgraph, Llocal, Lglobal, WGCNA, or STRING	Full model: 0.613; w/o masking: 0.609; w/o Lgraph: 0.605; w/o STRING: 0.604	Annealed masking and graph regularization are both necessary and complementary; STRING and WGCNA provide distinct value	That any single component is <i>sufficient</i> ; removal effects are additive, not synergistic	[Paper] [Paper: PDF p. 8] Table 2
Hyperparameter study (Table 3)	Optimal hyperparameters align with design intuition	Varying $f(t)$, $p_{\max}$, α on HMMVG-50	Best: $f(t)=t$, $p_{\max}=0.75$, $\alpha=0.6$	Proportional annealing is superior; strong but not excessive masking works best; modest preference for STRING prior is justified	That these hyperparameters are globally optimal across all datasets or gene panels; PAAD omitted from some rows [Paper] [Paper: PDF p. 9]	[Paper] [Paper: PDF p. 9] Table 3
Qualitative visualization (Fig. 3)	CorrFlow improves spatial pattern fidelity and gene-level PCC, especially for highly correlated genes	CorrFlow vs. STFlow on LYMPH_IDC sample NCBI68 (KRT7), gene-wise PCC scatter, top-AvgAbsCorr genes	Fig. 3(a): cleaner spatial gradients; Fig. 3(b): majority of points above diagonal; Fig. 3(c): higher PCC on top-correlated genes	Visual and gene-level evidence confirms quantitative gains reflect real biological improvement, not just metric artifact	That improvements hold for <i>all</i> marker genes or tissue contexts; only one sample visualized per dataset	[Paper] [Paper: PDF p. 9] Fig. 3

Experiment	Claim tested	Comparison and conditions	Result	Supported conclusion	Unsupported stronger conclusion	Source
Expanded gene sets (Table 4)	Dependency-aware design scales to broader gene panels	CorrFlow vs. STFlow on HMMVG-100/150/200	CorrFlow consistently outperforms (e.g., PCC-100: 0.591 vs. 0.584)	Benefit is not limited to highly variable marker genes but extends to larger, biologically relevant scopes	That performance gap <i>widens</i> with scale; margins are stable but moderate	[Paper] [Paper: PDF p. 14] Table 4
GGC-Pearson (Table 7)	CorrFlow better preserves gene-gene correlation structure	CorrFlow vs. STFlow on GGC-Pearson metric	CorrFlow: avg=0.648; STFlow: avg=0.633	Direct evidence that CorrFlow’s core claim—improving dependency structure—is empirically validated	That GGC-Pearson perfectly correlates with downstream biological utility; no such analysis performed	[Paper] [Paper: PDF p. 17] Table 7
Statistical significance (Table 12)	CorrFlow’s superiority is statistically robust at gene level	Paired Wilcoxon tests on pooled 500 gene-dataset pairs	All Holm-corrected $p < 10^{-16}$; vs. STFlow: mean diff=0.0129, wins=330/500	The observed PCC advantage is not due to chance or dataset-level averaging artifacts	That every single gene benefits; 170 losses indicate some genes are worse	[Paper] [Paper: PDF p. 19] Table 12

11 对结论的正确理解

论文结论应被理解为：在 HEST-1K 这一特定、泄漏控制的、患者分层的 benchmark 下，CorrFlow 通过其双机制设计，在 PCC/HPCC/GGC-Pearson 等指标上实现了统计显著且稳健的提升，且提升源于其对基因依赖的显式建模。这不是一个泛泛而谈的“更好模型”，而是对一个被严格证明存在的结构性缺陷（Proposition 1）的针对性修复。其结论成立的关键边界是：（1）评估基于 HMMVG-50 等预选基因集，而非全转录组；（2）依赖于 STRING/WGCNA 图的可用性与质量；（3）效果在 HEST-1K 内部 CV 上稳健，但尚未在完全独立外部队列上验证 [Paper] [Paper: PDF p. 19]。因此，正确理解是：“CorrFlow 为 histology-to-ST 生成提供了一种原理清晰、证据充分、在当前主流 benchmark 上有效的依赖感知范式”，而非“解决了所有 ST 生成问题”。

12 作者明确承认的限制

Limitation	Specific manifestation	Future direction proposed by authors	Source
Lack of external validation	Evaluation uses HEST-1K (diverse but internal) and STImage-1K4M (non-standard splits); no fully independent external cohort with different tissue prep, platform, scanner	Incorporate independently collected ST cohorts to rigorously evaluate out-of-distribution generalization	[Paper] [Paper: PDF p. 19]

Limitation	Specific manifestation	Future direction proposed by authors	Source
Insufficient clinical readiness	Prediction quality, while best-in-benchmark, remains insufficient for direct clinical translation due to intrinsic challenge of inferring molecular states from morphology alone	Improve robustness via stronger dependency-aware modeling and higher-quality ST training data	[Paper] [Paper: PDF p. 19]
Downstream utility unassessed	Current evaluation focuses on reconstruction fidelity (PCC) and structure preservation (GGC), not biological/clinical utility	Assess whether generated ST profiles benefit downstream tasks: tissue-domain identification, pathway activity estimation, biomarker discovery, patient stratification, prognosis modeling	[Paper] [Paper: PDF p. 19–20]

13 批判性分析

[Analysis] Observation	Potential issue or alternative explanation	Why it matters	How to test it	Basis
The "learnable mask token" m is shared across all spatial locations (n) and all genes (g) in the mask set M [Paper] [Paper: PDF p. 5], meaning it cannot encode gene-specific or location-specific masking semantics.	This design conflates two distinct concepts: (i) a generic placeholder for <i>any</i> masked gene, and (ii) a gene-specific prior (e.g., expected expression level of KRT7). A gene-specific token could better guide imputation.	If masking is meant to simulate biological uncertainty, a uniform token ignores known gene-specific baselines (e.g., housekeeping vs. low-abundance genes), potentially weakening the dependency signal.	Replace scalar m with gene-specific vector m_g ; compare PCC and gene-level error distribution (e.g., does KRT7 imputation improve more than background genes?).	[Paper] [Paper: PDF p. 5] "learnable gene-wise mask tokens $m \in \mathbb{R}^G$, shared across spatial locations"
The graph fusion weight $\alpha=0.6$ favors STRING over WGCNA [Paper] [Paper: PDF p. 9], yet Table 5 shows w/o STRING (0.604) hurts performance more than w/o WGCNA (0.607), suggesting STRING is more critical. However, STRING is static and may not reflect tissue-specific regulation.	Relying heavily on a static functional prior risks misalignment in contexts where co-expression diverges from protein interaction (e.g., post-transcriptional regulation, tumor-specific rewiring). The model may over-smooth tissue-specific signals.	This could explain why gains are larger on HPCC (pathway-focused) than on raw PCC, and why some datasets (e.g., HCC in Table 1) show large absolute PCC gaps but modest HPCC gaps.	Train separate models with $\alpha=0.0$ (WGCNA-only) and $\alpha=1.0$ (STRING-only); analyze per-dataset PCC/HPCC delta and correlate with tissue type (e.g., does $\alpha=1.0$ work better in homogeneous tissues like SKCM?).	[Paper] [Paper: PDF p. 9] Table 3 ($\alpha=0.6$ best), Table 5 (w/o STRING drop > w/o WGCNA drop)

[Analysis] Observation	Potential issue or alternative explanation	Why it matters	How to test it	Basis
The Huber loss (Eq. 11) and Laplacian loss (Eq. 12) both aim for smoothness but operate on different scales; however, the paper does not analyze whether they conflict (e.g., Lglobal may suppress biologically valid high-frequency variation captured by Llocal).	Over-regularization could flatten genuine biological heterogeneity, such as sharp expression boundaries between tumor and stroma, which are crucial for domain identification.	This directly impacts the "biological coherence" claim—if coherence means "smooth", it may sacrifice "spatially resolved biological accuracy".	Visualize Llocal and Lglobal gradients on a sample; compute spatial gradient magnitude of $\hat{x}_1$ before/after applying each loss term; correlate with ground-truth domain annotations.	[Paper] [Paper: PDF p. 6–7] Llocal for "pairwise consistency", Lglobal for "graph-wide patterns"; no conflict analysis

14 学到的知识

- **Flow matching 的结构性缺陷是可证明、可修复的：** Proposition 1 不是经验观察，而是从 CFM 目标函数导出的必然结论；Annealed-MFM 是其第一个被证明能改变最优解性质的修复方案（Proposition 2）。
- **掩码策略的设计必须与生成动力学耦合：** 简单随机掩码（如 BERT）无效； $p(t) \propto t$ 的 annealing 是针对 $t \rightarrow 1$ 时 shortcut 问题的精准干预，非启发式技巧。
- **生物学图谱应作为正则化器，而非特征编码器：** CorrFlow 不将 STRING/WGCNA 输入网络，而是将其转化为对 $\hat{x}_1$ 的软约束（Llocal/Lglobal），这更符合“先验应指导结果而非扭曲特征”的原则。
- **指标选择揭示建模意图：** HPCC (Eq. 13) 和 GGC-Pearson (Eq. 20) 不是锦上添花，而是 CorrFlow 核心主张的直接验证工具——它们量化了“通路级”和“基因对级”的一致性，比单一 PCC 更贴近论文目标。
- **计算效率与科学严谨可兼得：** CorrFlow 与 STFlow 参数量相同 (Table 14)，证明创新在 loss 设计而非模型规模，这对资源受限的 biomedical AI 研究极具借鉴价值。

15 与既有知识的连接

- **候选连接/方法论连接：** 本文的“annealed masking”与 single-cell foundation models 中的 masked autoencoding（如 scGPT）有形式相似性，但目标迥异——前者旨在诱导跨基因条件推理，后者旨在学习通用表征；CorrFlow 的图正则化与 spatial transcriptomics 中的 graph neural networks（如 SpaGCN [9]）共享图结构思想，但 SpaGCN 用于聚类/spot embedding，CorrFlow 将图嵌入生成动力学，属 novel application。
- **候选连接/方法论连接：** 其“dependency-aware generation”思路与 perturbation prediction 任务（如 CausalCell）高度共鸣——两者均需建模基因扰动后的联合响应，CorrFlow 的 annealed-MFM 可视为一种无扰动的、自监督的依赖发现机制。
- **候选连接/方法论连接：** multi-omics 对齐常依赖 cross-modal contrastive learning；CorrFlow 的 conditional flow matching on histology $\rightarrow$ ST offers an alternative generative alignment paradigm, where the “alignment” is enforced by the joint flow trajectory and graph constraints, not by shared latent space.

16 研究想法

[Hypothesis] 以下研究想法为基于论文证据和局限的可检验假设，不代表论文作者已验证。

- **name:** Gene-Specific Annealed Masking

originating limitation/observation: [Analysis] The shared learnable mask token m ignores gene-specific expression baselines and may weaken dependency signal [Paper] [Paper: PDF p. 5]. **core hypothesis:** Assigning gene-specific mask tokens m_g , initialized to gene-wise median expression from training data, will improve imputation accuracy for biologically relevant genes (e.g., markers) without harming others. **delta from paper:** Replace scalar m with vector $m \in \mathbb{R}^G$; initialize m_g to $\text{median}(x^1_g)$ over training spots. **initial method:** Implement in CorrFlow codebase; train on HEST-1K HMMVG-50; compare PCC per gene (especially top-10 AvgAbsCorr genes from Fig. 3c). **validation:** Significant PCC improvement (>0.02) on ≥ 5 marker genes (e.g., KRT7, CD44) with no degradation on housekeeping genes (e.g., ACTB, GAPDH). **failure modes:** Increased overfitting if m_g is over-optimized; failure to converge if initialization is poor. **innovation status:** unverified

- **name:** Dynamic Graph Fusion for Perturbation Context

originating limitation/observation: Static STRING/WGCNA fusion (Eq. 9) may misalign in perturbed states (e.g., drug treatment), where co-expression rewires [Paper] [Paper: PDF p. 9]. **core hypothesis:** A lightweight adapter that modulates α based on histology-derived perturbation cues (e.g., necrosis, mitotic count) will improve ST prediction under intervention. **delta from paper:** Replace fixed α with $\alpha = \sigma(Wz + b)$, where z is histology feature vector, σ is sigmoid. **initial method:** Add adapter head to UNI encoder; train end-to-end on simulated perturbation dataset (e.g., HEST-1K + synthetic drug-response patches). **validation:** On held-out perturbed samples, achieve >0.03 PCC gain over fixed- α CorrFlow and >0.05 over STFlow. **failure modes:** Adapter collapses to constant α ; introduces noise that degrades baseline performance. **innovation status:** unverified

- **name:** Cross-Modal Alignment via Joint Flow Trajectories

originating limitation/observation: CorrFlow aligns histology $\rightarrow$ ST, but multi-omics requires alignment across modalities (e.g., ATAC+RNA); its flow matching framework is inherently extendable. **core hypothesis:** Modeling ATAC $\rightarrow$ RNA and histology $\rightarrow$ RNA as *joint* conditional flows (with shared graph regularization) will improve cross-modal imputation consistency. **delta from paper:** Extend CorrFlow to multi-condition: $v\theta(\sim xt, t, c_{\text{histology}}, c_{\text{atac}})$; share Lgraph across modalities; add modality-specific masking. **initial method:** Adapt to paired ATAC/RNA/histology dataset (e.g., SNARE-seq + H&E); use same STRING+WGCNA graph; report joint PCC and cross-modal correlation preservation. **validation:** Joint model achieves higher GGC-Pearson on RNA than either single-modality model, and improves ATAC $\rightarrow$ RNA PCC by >0.02 . **failure modes:** Optimization instability from multi-condition input; graph regularization over-constrains modality-specific signals. **innovation status:** unverified
